Abstract: Babesiosis is the only intraerythrocytic parasitic disease that affects horses. Signs include fever, depression, anorexia, weakness, ataxia, lacrimation, mucoid nasal discharge, icterus and hemoglobinuria. Death may occur within 48 hours or chronic cases may persist for months. In May 2001, a three year old cross-bred mare was referred to the veterinary teaching hospital of Kerman university, with anorexia and depression for five days and jaundice in conjunctiva. Hematological examination revealed a PCV of 40. In the blood smear, *Babesia equi* was observed and typified. Treatment was performed by Imizol (4mg/kg, im) for three days. The animal got better and vital signs were normal after completion of the treatment. The mucous membrane was completely normal and the appetite was normal as well.

Key words: babesiosis, horse, Imizol, icterus.

Introduction

Babesiosis is a tick-borne intraerythrocytic disease of domestic and wild mammals and man caused by protozoan parasites of the genus *babesia*. The disease in horses is caused by *Babesia cabali* (large *babesia*) and *Babesia equi* (small *Babesia*). Equine Babesiosis is widely distributed throughout the tropics and subtropics and to a lesser extent in temperate regions. All equids are susceptible and older animals are more severely affected. The disease is a major problem in transition of horses among countries (1, 2, 6, 13, 7, 8). Once they gain access to the host, *Babesia* species multiply and develop within erythrocytes. Many parasitized erythrocytes are removed via the macrophages; however, intravascular hemolysis can occur. Definitive diagnosis of babesiosis relies upon the demonstration of parasitized erythrocytes on Giemsa-stained blood smears or by positive serology.

Case Report

A three year old cross-bred mare (kord-Arabian) was referred to the veterinary teaching hospital of

Kerman university, with anorexia and depression for five days and jaundice in conjunctiva. There was no history of treatment and the diet was alfalfa hay, straw and barely. On physical examination, the temperature was 38.8 °C, the respiratory rate was 12 p/min and the pulse rate of 46 bpm. There was no abnormality in any other organs except jaundice in mucous membranes and some ulcers in the skin, specially in the forelimbs and a mild colic. Hematological examination revealed a PCV of 40%, WBC of 9000 u/L (55% neutrophils, 24% lymphocytes, 18% monocytes and 3% eosinophils. In the blood smear, *Babesia equi* was observed and typified. After final diagnosis, treatment was performed by Imizol (4mg/kg, IM, sid) for three days. Additional treatments were catosal (phosphorus)10 ml for three days, vitamin B12 and two liters of paraffin for the relief of colic. After three days of treatment, the animal gradually got better and vital signs were normal. The hematological values were within normal limits and no *babesia* was found in the RBC. The mucous membranes were completely normal and the appetite was normal. One week later, the animal was completely recovered.

Discussion

All equids are susceptible to both *Babesia caballi* and *Babesia equi* that cause babesiosis in the animal. Older animals are more severely affected than young animals, once infected, survivors remain chronic carriers (4,15).

Clinical features of the disease following an incubation period of five to twenty-eight days are fever (39-42°C), hemolytic anemia, jaundice, hemoglobinuria and death. Generalized signs of depression, anorexia, incoordination, lacrimation, mucous nasal discharge, swelling of eyelids and frequent lying down are also seen. *Babesia equi* is considered the most pathogenic of the two species and *Babesia caballi* causes a more persistent fever and anemia (3, 5, 11, 12, 15).

Clinically, jaundice with hemoglobinuria and fever is suggestive, but confirmation by examination of blood smears or by transmission experiments is essential. A necropsy which shows splenomegaly, jaundice, hemoglobinuria, swollen dark kidneys, liver and myocardial echymosis, while highly suggestive, should also be confirmed by laboratory examination (3, 5, 11, 12).

In the present case, depression, fever, anorexia and jaundice were the most apparent clinical signs and the presence of *babesia* (*B. equi*) in the blood smear was also confirmed. The drug of choice for eliminating the carrier state of infected animals is Imidocarb.

Imidocarb at the level of 2.2 mg/kg given two times at a 24-hours interval is effective against *B. caballi*, a 4 mg/kg amount given four times at a 72-hours intervals effective for *B. equi*. The higher doses of Imidocarb often produce transient side effects in horses similar to the signs seen in colic (9, 10, 11, 14, 15).

Babesia equi is much more resistant and imidocarb therapy is only 50% to 60% effective in eliminating the infection, particularly of eastern European origin. Imidocarb may cause colic, hypersalivation, diarrhea and death.

In the present case, the treatment dose of 4 mg/kg for three days at 24 hours interval was considered. The animal was completely recovered after a week

and no side effects of the drug were seen.

در تاریخ اردیبهشت ۱۳۸۰ یک مادیان دو خون کرد - عرب ارجاعی به درمانگاه دانشکده دامپزشکی دانشگاه شهید باهنر کرمان مورد معاینه قرار گرفت. شکایت اسیدار مبتنی بر کاهش اشتها و افسردگی به مدت ۵ روز وجود زردی در مخاط چشم بود. هیچ درمانی برای حیوان انجام نشده و حیره غذایی حیوان شامل یونجه و مقداری کاه جو بود. در معاینه بالینی در جه حرارت و ضربان قلب حیوان بالاتر از حد طبیعی ثبت شد و زردی در تمام مخاطلات مشاهده گردید. همچنین تعدادی رخمهای پوستی نیز خصوصاً در دستهای حیوان مشاهده شد. در گسترش خون محیطی وجود تک یاخته بازیاقطعی شد و با مطالعه مرفلوژیک گونه آن بازیابیاکوئی تشخیص داده شد. درمان با استفاده از ترکیب ایمی زول (۴ میلی گرم بر کیلوگرم) به مدت ۳ روز و درمان‌های کمکی فسفر و ویتامین ب ۱۲ و پارافین انجام گرفت. حیوان بعد از درمان به تدریج وضعیت بهتری بخود گرفت و علایم حیاتی و آزمایش‌های خونی بعد از یک هفته کاملاً به حالت طبیعی برگشت. با بررسی منابع در کل درمان موارد حاد بیماری عاقبت خوبی ندارند و این موارد به خوبی بازدیدکتر کردن فاصله بین درمان‌ها بدون بروز هیچ‌گونه اثرات جانبی به درمان جواب داد.

واژه‌های کلیدی: بازیوز، اسب، ایمینزول، تیرمان.
