ABSTRACT

The identification of the efficiency of some mtDNA genes of *Mus musculus* species complex (house mouse) for biosystematics research was studied in this approach. Recent studies have made use of different mitochondrial genes including NADH dehydrogenase genes, cytochrome b gene, cytochrome oxidase genes, D-loop region and whole mtDNA genome to study the house mouse species. Usage of each of these genome regions has its own advantages and disadvantages. Identification of appropriate genomic regions is very important for molecular biosystematic research. We have shown here that NADH dehydrogenase and Cytochrome oxidase genes (particularly COX2) are especially useful in biosystematics studies and subspecies identification, whereas D-loop region is the best candidate for biogeographic and phylogeographic studies of subspecies of this species efficiency-wise as well as economically. These candidates are introduced considering that the first two gene complexes are highly conserved whereas the latter is well receptive to gaining and preserving the mutations through time.

Key Words: biosystematics, house mouse subspecies (*Mus musculus*), mitochondrial genes, phylogeography.

Introduction

The house mouse complex includes different subspecies among which the consensus ones are: *Mus musculus domesticus* (found in Western Europe, north of Africa and Middle East), *M. m. musculus* (found in Eastern Europe and north of Asia) and *M. m. castaneus* (found in south-eastern Asia) (1, 2). Besides these three consensus subspecies, two other subspecies are also present in NCBI (<http://www.ncbi.nlm.nih.gov>): *M. m. molossinus* and *M. m. gentilulus*. The 16Kb long mammalian mitochondrial genome is circular and holds 13 protein coding genes: seven NADH dehydrogenase complex genes (MT-ND1, MT-ND2, MT-ND3, MT-ND4, MT-that encode to ATP synthase subunits (MT-ATP6, MT-ATP8); and one cytochrome b gene (MT-CYB) In addition, 24 RNA coding, 22 tRNA coding and two rRNA coding genes are also present in the mitochondrial genome (3).

The mitochondrial cytochrome *b* gene product forms part of complex III of the mitochondrial respiratory chain in eukaryotes as well as aerobic prokaryotes. The nucleotide diversity of this gene has resulted in its wide use in phylogenetic analyses especially at family, genus and species levels (4). Cytochrome oxidase mitochondrial genes make up parts of complex IV subunits of the respiratory chain; these are also used to investigate phylogenetic relationships (5, 6). NADH dehydrogenase complex constitutes complex I of the respiratory chain. This complex enzyme possesses 45 subunits in mammals of which seven are coded by mitochondrial genes (7).

Since, NADH dehydrogenase, cytochrome oxidase and cytochrome *b* are part of the mitochondrial respiratory chain, their corresponding mitochondrial genes are

constantly being transcribed in order to produce new complexes to replenish enzymes of the aerobic respiratory machine of the cell. Additionally, all these coding genes are under natural selection and therefore mutations in the genes are poorly tolerated. The D-loop which contains the origin of replication of the mitochondrial genome is also constantly operational as mitochondrion replication occurs independently from nucleus replication. However, since the D-loop region does not code for any product, it is under less stringent natural selection; therefore, this region's mutations are better tolerated and selected against to a lesser degree. As a result, D-loop is widely used as a significant marker in phylogeographic studies. The mitochondrial genome is popular for population and evolutionary studies in animals because of relative ease of isolating and comparing homologous sequences, simple sequence organization, maternal inheritance, absence of recombination (in most but not all cases), and rapid rate of sequence divergence (8).

Several studies have been conducted on the house mouse exploiting mitochondrial genome in recent years(1,2,8-31) These studies have made use of a variety of genes among which the most popular include: NADH dehydrogenase, cytochrome *b*, cytochrome oxidase, d-loop, and whole mitochondrial genome. Considering the wide range of the employed genes, it seems crucial to carry out a comprehensive study so as to reach comparative results concerning the value of usage of these genes in biosystematic investigations.

The present study evaluated the efficacy of the sequences of these genes in proper separation and classification of house mouse subspecies and to draw reliable phylogenetic trees based on them. Bearing in mind how time-consuming and costly molecular studies are,

selecting the appropriate gene is an extremely important step in such studies. Findings of comparative studies as the present one could lead to great saving of time and expenses in molecular biosystematic studies.

Materials and methods

NADH dehydrogenase complex, cytochrome *b*, cytochrome oxidase complex, D-loop and complete mitochondrial genome sequences ($n=713$) of house mouse subspecies (*Mus musculus castaneus*, *M. m. musculus*, *M. m. domesticus*, *M. m. molossinus*, and *M. m. gentilulus*) were obtained from NCBI (Table 2). Sequences were aligned with Mega5 using Clustal W alignment procedure (32). The corresponding gene sequences of *Mus macedonicus* and *Mus terricolor* were used as outgroups in each analysis. Using Mega5 program (www.megasoftware.net) the Neighbor-joining trees were depicted with a bootstrap of 1000 and complete deletion of the sites including gaps options. Overall mean distance values were also calculated for the sequences to evaluate the mean number of nucleotide substitutions per each nucleotide site. Using DnaSP v5 (33), haplotypes were identified and the haplotype NJ tree was generated by Mega5.

Results

The genealogical tree was depicted for each investigated genes, using Neighbor-Joining distance matrix. In order to evaluate the genes' efficacy, each data set was separately analyzed.

Cytochrome *b*: Robustness of branches and reliability of gene tree was displayed by high bootstrap values on each branch (Fig. 1). It is to be born in mind that though some individuals belong to a certain subspecies according to morphological characteristics, based on cytochrome *b* gene they fall within another subspecific group; for instance, though individuals AB205277, AB205278, and AB205279 are identified as *M. m. castaneus* on NCBI, they fall into *M. m. domesticus* subspecies clade based on their cytochrome *b* sequence. All individuals of the *M. m. molossinus* subspecies fall into clade of the *M. m. musculus* subspecies inferring their genetic vicinity. The individual AB208250c belonging to *M. m. castaneus* subspecies has a position between *castaneus* and *musculus/molossinus* clades; as asserted by the corresponding researcher there has been the multiple errors in the sequence deposited in the GenBank (34).

Table 1. The sample size of each subspecies downloaded from NCBI.

subspecies	MtDNA	D-loop	NADH dehydrogenase	Cyt Oxidase	Cytb
<i>Mus musculus domesticus</i>	33	409	33	33	25
<i>M. m. castaneus</i>	2	101	2	2	9
<i>M. m. musculus</i>	3	11	3	3	4
<i>M. m. molossinus</i>	3	3	3	3	3
<i>M. m. gentilulus</i>	-	7	-	-	-
<i>M. terricolor</i>	2	-	2	2	-
<i>M. macedonicus</i>	-	10	-	-	2

Table 2. Detailed information of the sequences used in the analyses.

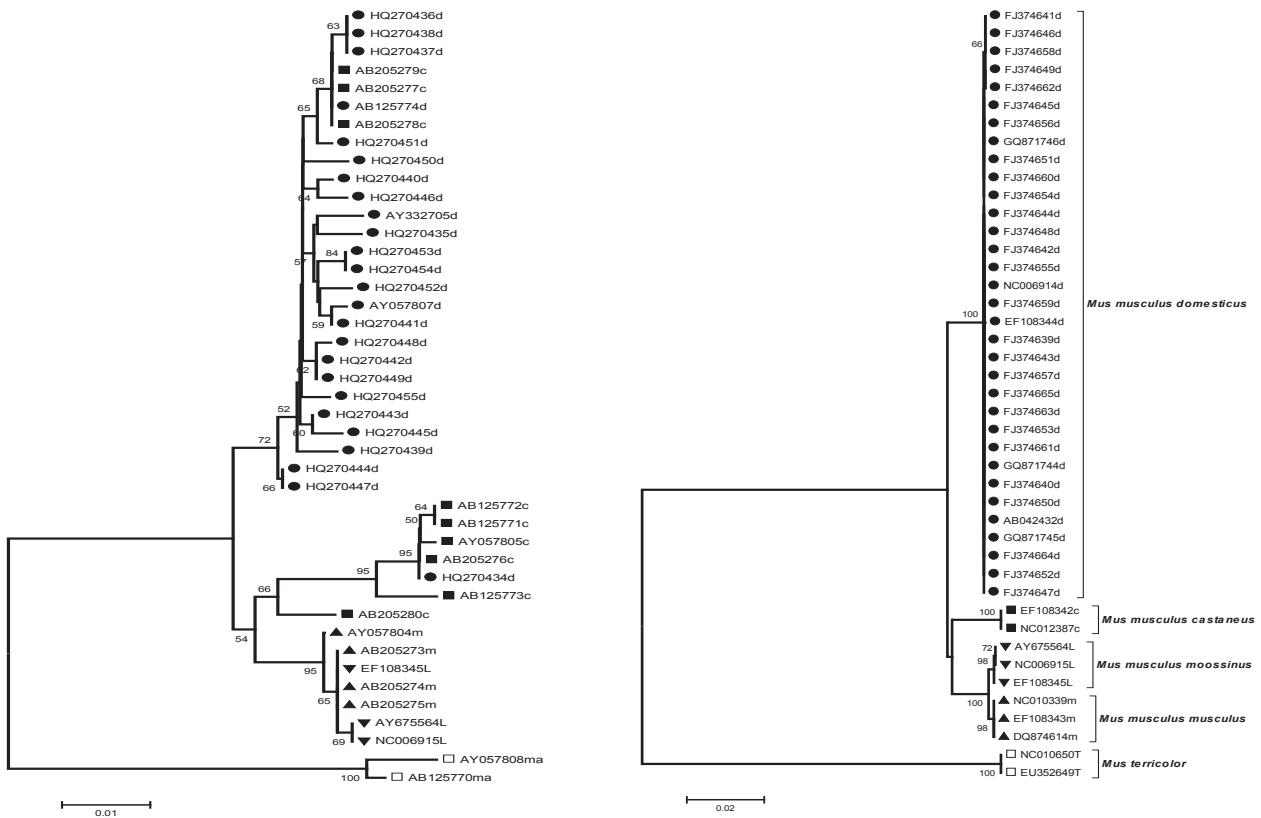

Figure 1. Neighbor-joining tree based on Tamura-3-parameter distance using Cytochrome b sequences. The numbers on each branch correspond to bootstrap support for all major lineages (percentages lower than 50 are not shown). The tree was rooted with two *M. macedonicus* sequences. The geometric shapes on tips of branches correspond to the different subspecies of mice: solid triangle, *Mus musculus* musculus; inverted solid triangle, *M. m. molossinus*; solid circle, *M. m. domesticus*; solid square, *M. m. castaneus* and open square, *M. macedonicus* as outgroups).

Cytochrome oxidase: As the gene genealogy of cytochrome oxidase clearly shows (Fig. 2), this gene complex has more successfully separated the house mouse subspecies than cytochrome *b* (Fig. 1). Another point of interest is the high conformity between the morphological identification of the subspecies as identified using NCBI and their grouping based on cytochrome oxidase

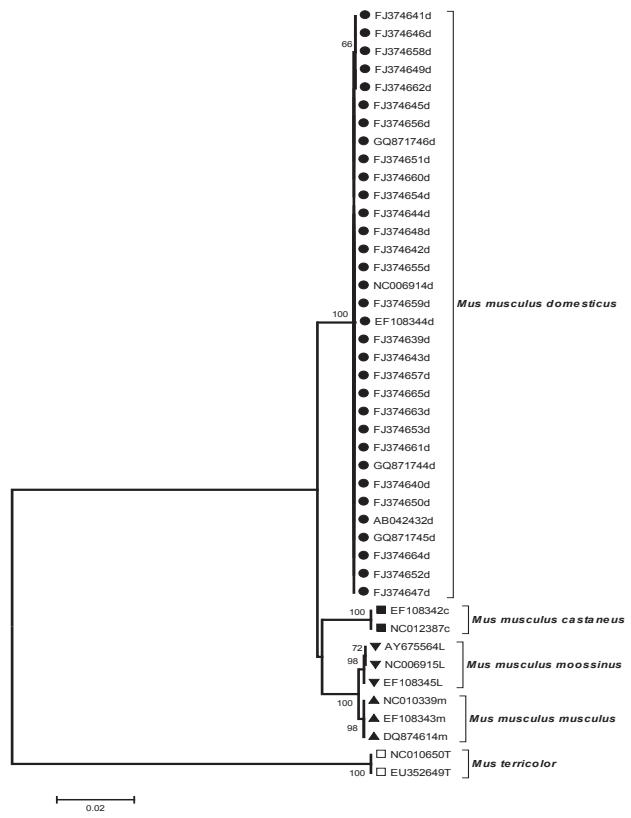

Figure 2. Neighbor-joining tree based on Tamura-3-parameter distance using Cytochrome oxidase sequences. The numbers on each branch correspond to bootstrap support for all major lineages (percentages lower than 50 are not shown). The tree was rooted with two *M. terricolor* sequences. The geometric shapes on tips of branches correspond to the different subspecies of mice: solid triangle, *Mus musculus* musculus; inverted solid triangle, *M. m. molossinus*; solid circle, *M. m. domesticus*; solid square, *M. m. castaneus* and open square, *M. terricolor* as outgroups).

gene complex which could be considered as an advantage in conducting biosystematic studies.

NADH dehydrogenase complex: NADH dehydrogenase complex also shows an excellent ability to separate the house mouse subspecies properly (Fig. 3; all bootstrap values are higher than 87%) Analyses based on this gene complex, as seen with cytochrome oxidase,

Figure 3. Neighbor-joining tree based on Tamura-3-parameter distance using NADH dehydrogenase sequences. The numbers on each branch correspond to bootstrap support for all major lineages (percentages lower than 50 are not shown). The tree was rooted with two *M. terricolor* sequences. The geometric shapes on tips of branches correspond to the different subspecies of mice: solid triangle, *Mus musculus* *musculus*; inverted solid triangle, *M. m. molossinus*; solid circle, *M. m. domesticus*; solid square, *M. m. castaneus* and open square, *M. terricolor* as outgroups).

yields a phylogenetic grouping in complete conformity with the primary morphological identification presented on NCBI; in other words, the individuals possessed the NADH dehydrogenase gene complexes belonging to their own subspecies.

D-loop: The coalescent NJ tree generated for all data set used in this analysis, is displayed in Figure 4. D-loop sequence also demonstrates satisfactory efficiency in proper separation of house mouse subspecies, though bootstrap values are not as high as those of cytochrome oxidase, cytochrome *b*, NADH dehydrogenase, and complete mitochondrial genome sequences. High diversity is present within *Mus musculus* *castaneus* subspecies which could be grouped into three particularly distinct groups; this is consistent with the results of a study by Hassan Rajabi-Maham and his co-workers (34) Here also

there are some individuals for whom the D-loop grouping does not comply with their morphologically identified subspecies as presented in NCBI. This is particularly evident between *Mus musculus* *musculus* and *M. m. domesticus* which is not unexpected because they have a recognized hybrid zone in Central and Western Europe (2). Since the many individuals were present in the analysis, haplotype trees could be derived. A haplotype tree was depicted after identifying the haplotypes: D-loop haplotype tree in Fig. 5 also shows good efficiency of this gene in separating different house mouse species. In this tree too, at least three distinct groups can be observed within *M. m. castaneus*. A close relationship between *Mus musculus* *castaneus* and *M. m. musculus* is observable. Additionally, the closest subspecies to *M. m. domesticus* is clearly *M. m. gentilulus*.

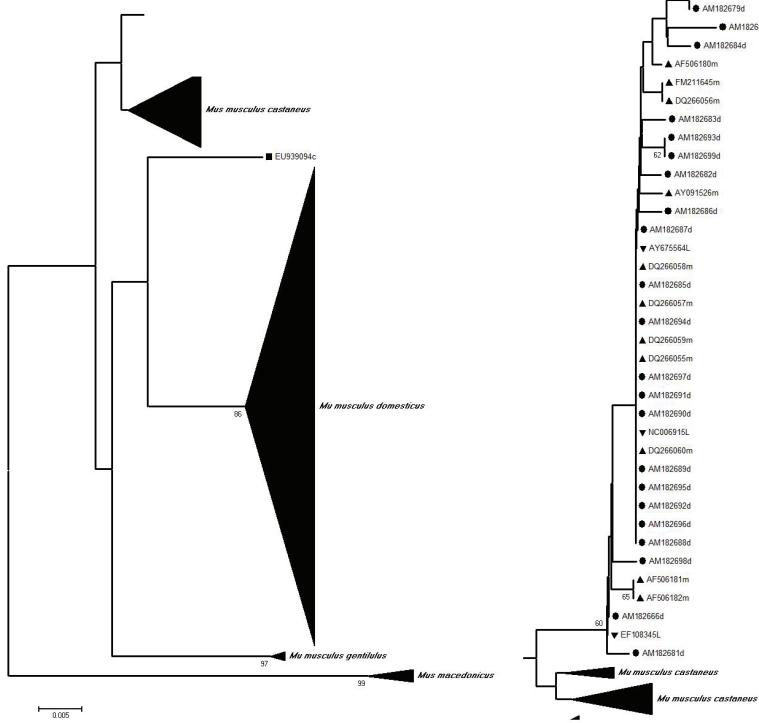

Figure 4. Neighbor-joining tree based on Tamura-3-parameter distance using D-loop sequences. The numbers on each branch correspond to bootstrap support for all major lineages (percentages lower than 50 are not shown). The tree was rooted with a single *M. macedonicus* sequences. The geometric shapes on tips of branches correspond to the different subspecies of mice: solid triangle, *Mus musculus* *musculus*; inverted solid triangle, *M. m. molossinus*; solid circle, *M. m. domesticus*; solid square, *M. m. castaneus* and as outgroup, *M. macedonicus*).

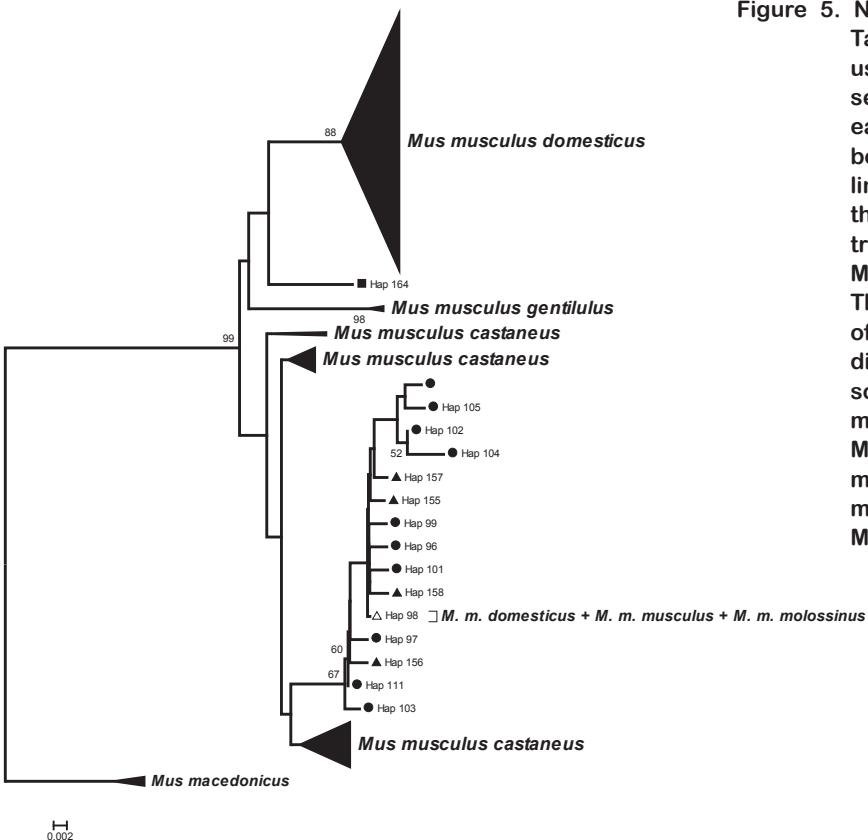

Figure 5. Neighbor-joining tree based on Tamura-3-parameter distance using D-loop haplotype sequences. The numbers on each branch correspond to bootstrap support for all major lineages (percentages lower than 50 are not shown). The tree was rooted with a single *M. macedonicus* sequences. The geometric shapes on tips of branches correspond to the different subspecies of mice: solid triangle, *Mus musculus* *musculus*; inverted solid triangle, *M. m. molossinus*; solid circle, *M. m. domesticus*; solid square, *M. m. castaneus* and open square, *M. macedonicus* as outgroup).

Complete mitochondrial genome: As expected, obtained trees using the complete mitochondrial genome sequence demonstrated

the best separation pattern among subspecies (Fig. 6)

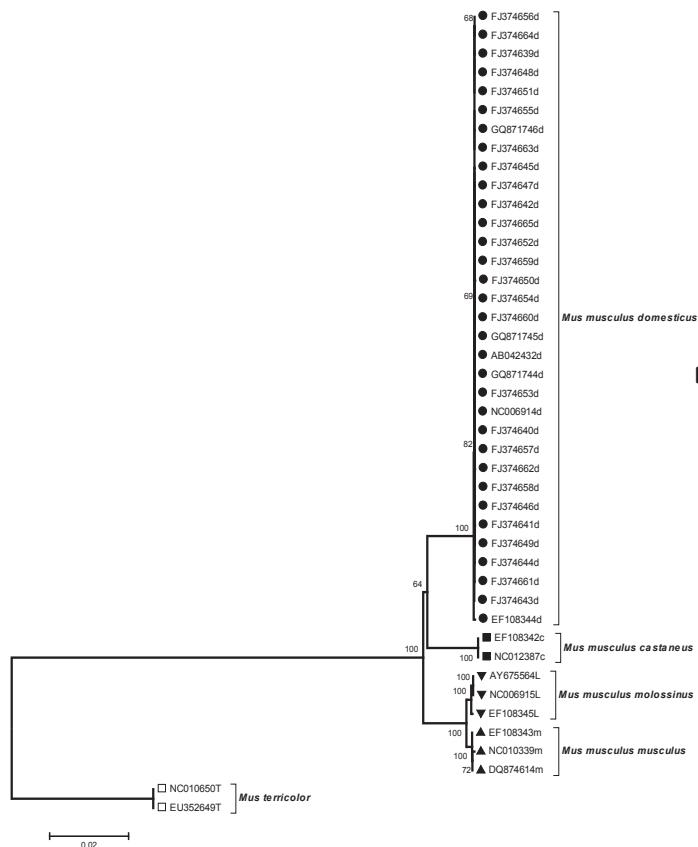

Figure 6. Neighbor-joining tree based on Tamura-3-parameter distance using complete mitochondrial genome sequences. The numbers on each branch correspond to bootstrap support for all major lineages (percentages lower than 50 are not shown). The tree was rooted with two *M. terricolor* sequences. The geometric shapes on tips of branches correspond to the different subspecies of mice: solid triangle, *Mus musculus* *musculus*; inverted solid triangle, *M. m. molossinus*; solid circle, *M. m. domesticus*; solid square, *M. m. castaneus* and open square, *M. terricolor* as outgroups).

Overall mean distance

Results of the overall mean distance measurements showed that considering the length of the sequences, the greatest rate mutation is observed in D-loop and cytochrome *b* which make these genes appropriate for use in phylogeographic studies (mtDNA complete genome = 0.14, Cytochrome oxidase = 0.14, Cytochrome *b* = 0.22, NADH dehydrogenase = 0.25, D-loop = 0.25).

Discussion

Results of this comparative analysis reveals that the best tool of genome typing for to

be used for distinguishing house mouse subspecies is the complete mitochondrial genome. The sequences of the NADH dehydrogenase complex and cytochrome oxidase genes are the best alternative, followed by D-loop and cytochrome *b* gene sequences. As a common rule, the more nucleotide site sequences are used, the better the differentiation of subspecies; NADH dehydrogenase complex gene which harbors the second highest number of nucleotide site (6332 sites) among the sequences tested, demonstrates a remarkable efficiency in distinction of individuals at the subspecies level.

We propose cytochrome oxidase gene with a length of about 3017bp as the most economical and efficient gene for biosystematic studies; it had a high resolution for house mouse subspecies differentiation. Within this gene complex, the proper part is COX2 with a length of 684 bp and 93 informative nucleotide sites in this analysis. Except D-loop region gene, all parts of the mitochondrial genome studied here are coding regions. The coding sequences are sensitive to natural selection and therefore nucleotide changes are not preserved and passed to the next generations. However, the D-loop is a non-coding region and possesses hypervariable segments; mutations therein are preserved through generations and thus can be used as an efficient evolutionary marker to trace matrilineal coalescent in population genetic and phylogeographic studies.

Hence, the wide exploitation of D-loop in phylogeographic studies of *Mus musculus* complex is understandable with regards to its relatively short length of about 900bp (with respect to costs of sequencing) and its appropriateness for being used in an array of different studies. Individuals of *M. m. domesticus* and *M. m. musculus* were observed

close to each other probably due to the Central and Western Europe hybrid zone (2) which allows genetic flow between these two subspecies; ergo, genetic similarities between these two subspecies is not unexpected. However, low introgression of NADH dehydrogenase and cytochrome oxidase gene complexes among subspecies indicated the probable incompatibility constrains in hybrid formation among subspecies. These genes seem to be subspecies-specific and like many other autosomal and sexual chromosome genes which are subject to natural selection, sequence variations in the gene are uncommon.

Coexistence of *M. m. molossinus* and *M. m. musculus* in all genealogic trees indicates their genetic vicinity and the greater mitochondrial similarity between them (35). As d-loop coalescent trees show, three completely distinct groups are identifiable within the heterogeneous *M. m. castaneus* group. This could be due the wide geographical distribution of this subspecies. Furthermore, proximity of them to the origin of house mouse could also justify such diversity.
