## Abstract

An effort has been made in modifying the radial distances of existing radial basis functions (RBFs) for the buckling analysis of functionally graded material (FGM) rectangular plates. The governing differential equations (GDE's) and boundary conditions are developed by employing the energy principle. The novelty of the present modified RBFs is that they are suitable for analyzing plates with varying aspect ratios. In the present analysis, thirteen different RBFs available in the literature are analyzed. It is found that all RBFs are well suited for buckling analysis of FGM plates with a different aspect ratio which was not possible with existing RBFs. Existing RBFs were suitable for analyzing square plates. To demonstrate the accuracy and efficiency of the present method, results are obtained for the buckling load parameters with modified radial distances for different aspect ratios. The results of several numerical examples have shown that the present modified RBF-based meshfree methods are well suited and accurate for analyzing rectangular plates. The effect of aspect ratio with grading index, span to thickness ratio on the normalized critical buckling load is discussed.

**Keywords:** Rectangular plate; FGM; RBF; Meshfree; Buckling

## 1. INTRODUCTION

Radial basis function (RBF) based meshfree methods are effective techniques that have been widely implemented for multivariate data fitting over scattered data. This method is mainly applied to solve higher order partial differential equation problems with high convergence order numerically. Therefore, RBF-based meshfree methods have attracted many researchers in the recent past. The RBF method proposed as a multi quadric method was firstly implemented by Hardy [1] in 1971, and after almost two decades, Kansa [2, 3] has implemented the multiquadric radial basis function (MQ-RBF) method to solve various kinds of partial differential equations (PDEs). Many researchers and scientists have found the optimal shape parameter utilized in the MQ-RBF[4-8]. Fasshauer [9] explored a relation between multigrid finite elements and multilevel RBF with smoothing. Wendland[10] combined the RBFs with the field of Galerkin methods to solve PDEs. Farahani et al. [11] explained the optimal shape parameter of Wendland's RBF for

bending analysis of plates. Ferreira et al. [12-20] utilized the RBFs based meshless method for the analysis of plates and shells. Xiang et al.[21-25] utilized inverse multiquadric, Gaussian, and thin-plate spline RBFs based meshless method for the analysis of plates. Rodrigues et al.[26] implemented the RBFs -finite differences technique for the structural analysis of laminated plates. Roque et al.[27] used the RBF-Finite differences collocation method for the analysis of composite plates. Jeeoot [28-38] used RBF based meshless method for the analysis of square plates. Kumar et al. [39-47] used different types of RBFs for the analysis of FGM plates. Neves et al.,[48-50] used the RBF method to analyse FGM plates and shells. Maturi et al. [51] investigated static and free vibration analysis of sandwich plates by using the RBF technique.

Recently, many researchers have done various studies on the buckling and vibration analysis of plates in order to use it effectively and efficiently but buckling analysis by meshfree methods is available very few.

Thai et al.[52] investigated static, dynamic, and buckling analysis of FGM and sandwich plate by using modified Moving Kriging (MK) interpolation-based meshfree method. Bui et al.[53] investigate buckling analysis using the meshfree method under uniformly uniaxial, biaxial, and pure shear loads. Rodrigues et al.[54] investigated bending, vibration, and buckling analysis of laminated plates based on RBFs-differential quadrature collocation. Chu et al. [55] used the Hermite radial basis function collocation method for the buckling analysis of the FGM plate.. Many research work[56-62] carried out for the buckling analysis of plate and shells via nonlocal elasticity theory. Liew et al.[63] used meshfree method for buckling and vibration analysis of plates based on FSDT formulation. Zhang et al. [64] implemented Kriging meshless method for thermal buckling of FGM plates. Tan et al. [65] used an Isogeometric-meshfree technique for the analysis of 3D FGM plates and shells. Zarei and Khosravifard [66] investigated static and buckling analysis using the meshfree technique. The numerous papers published to offer the detailed study on vibration of plates, shell, and structure [56-59, 61, 67-105] . Hosseini et al. [106] investigated the effect of various parameters on the stress analysis of rotating nano-disk made of FGMs. Nejad et al. [107] studied the static analysis of the BDFG nano-beam via the Rayleigh-Ritz method. Khoram et al. [108] used the Eringen's nonlocal elasticity theory to study the mechanical behaviour of the nanobeam. Do et al. [109] investigated thermal buckling of FGM plate by using improved radial point interpolation function. Asemi et. al [110] examined the post-buckling analysis of orthotropic single-layered graphene sheet applying the nonlocal theory via Galerkin method. Hadi et al. [111] utilized the energy method and stress analysis to investigate the stresses and strains of a FGM beam subjected to an arbitrary transvers loading. Farajpour et. al [94] proposed a new explicit formula for the length-dependent persistence length of microtubules with consideration of surface effects. Farajpour et. al [103] proposed a new size-dependent plate model based on the higher-order nonlocal strain gradient theory for the buckling of nanoplates. Mohammadi et. al [98] studied the free vibration behaviour of rectangular graphene sheet under shear in-plane load by applying nonlocal elasticity theory. Mohammadi et. al [92] investigated the effect of the temperature change on the vibration frequency of elastically supported mono-layer graphene sheet via nonlocal elasticity theory.

To the best of authors' knowledge, few efforts of researchers have been paid on the performance of RBF-based meshfree method in investing FGM rectangular plate. Up to now, there does not exist a proper way to investigate the rectangular plate without changing the shape parameters, and it is still an important issue in the RBFs based meshfree method to determine the rectangular plate without changing shape parameters. The present study addresses, for the first time, a five variable HSDT for buckling analysis of FGM rectangular plate by using thirteen MRBFs based meshfree method. The newly proposed expression for MRBFs is implemented and successfully applied for the analysis of rectangular FGM plates.

## 2 MATHEMATICAL FORMULATIONS

Consider rectangular FGM plate with dimensions  $(a \times b \times h)$  in the cartesian coordinate system  $(x-y-z)$ . The mid-plane of the plate is considered the reference plane. The displacement field  $u$ ,  $v$ , and  $w$  at any point along the  $x$ -,  $y$ - and  $z$ -axes can be expressed as in terms of the mid-plane displacements  $u_0$ ,  $v_0$ ,  $w_0$  and rotations  $\phi_x$  and  $\phi_y$ .

$$\begin{aligned} u &= u_0(x, y) - z \frac{\partial w_0(x, y)}{\partial x} + f(z)\phi_x(x, y) \\ v &= v_0(x, y) - z \frac{\partial w_0(x, y)}{\partial y} + f(z)\phi_y(x, y) \\ w &= w_0(x, y) \end{aligned} \quad (1)$$

Where,  $f(z) = p \left( \left( \frac{z}{h} \right)^3 - \frac{3}{4h} z \right)$  is transverse shear function.

The volume fraction of the metal phase is obtained by.

$$V_m(z)=1-V_c(z) \tag{2}$$

The material property variation along the plate thickness is given by the following relations,

$$E(z)=[E_c - E_m] \left(\frac{2z+h}{2h}\right)^n + E_m \tag{3}$$

$$\rho(z)=[\rho_c - \rho_m] \left(\frac{2z+h}{2h}\right)^n + \rho_m \tag{4}$$

In the above equations, the young’s moduli of the metallic and ceramic constituents are given by  $E_m$  and  $E_c$  respectively. The material properties vary according to the power-law distribution where ‘n’ represents the grading index.

Strain-displacement relations are expressed as:

$$\left\{ \begin{matrix} \epsilon_{xx} \\ \epsilon_{yy} \\ \gamma_{xy} \end{matrix} \right\} = \left\{ \begin{matrix} \frac{\partial u}{\partial x} \\ \frac{\partial v}{\partial y} \\ \frac{\partial u}{\partial y} + \frac{\partial v}{\partial x} \end{matrix} \right\} = \left\{ \begin{matrix} \frac{\partial u_0}{\partial x} - z \frac{\partial^2 w_0}{\partial x^2} + f(z) \frac{\partial \phi_x}{\partial x} \\ \frac{\partial v_0}{\partial y} - z \frac{\partial^2 w_0}{\partial y^2} + f(z) \frac{\partial \phi_y}{\partial y} \\ \frac{\partial u_0}{\partial y} + \frac{\partial v_0}{\partial x} - 2z \frac{\partial^2 w_0}{\partial x \partial y} + f(z) \frac{\partial \phi_x}{\partial y} + f(z) \frac{\partial \phi_y}{\partial x} \end{matrix} \right\} \tag{5}$$

And,

$$\left\{ \begin{matrix} \gamma_{yz} \\ \gamma_{zx} \end{matrix} \right\} = \left\{ \begin{matrix} \frac{\partial v}{\partial z} + \frac{\partial w}{\partial y} \\ \frac{\partial u}{\partial z} + \frac{\partial w}{\partial x} \end{matrix} \right\} = \left\{ \begin{matrix} \frac{\partial f(z)}{\partial z} \phi_y \\ \frac{\partial f(z)}{\partial z} \phi_x \end{matrix} \right\} \tag{6}$$

The stress-strain relation using Hook’s law with respect to the structural axis system (X-Y-Z) for the FGM plate may be expressed as :

$$\left\{ \begin{matrix} \sigma_{xx} \\ \sigma_{yy} \\ \sigma_{xy} \\ \sigma_{yz} \\ \sigma_{zx} \end{matrix} \right\} = \left[ \begin{matrix} \bar{Q}_{11} & \bar{Q}_{12} & 0 & 0 & 0 \\ \bar{Q}_{12} & \bar{Q}_{22} & 0 & 0 & 0 \\ 0 & 0 & \bar{Q}_{66} & 0 & 0 \\ 0 & 0 & 0 & \bar{Q}_{44} & 0 \\ 0 & 0 & 0 & 0 & \bar{Q}_{55} \end{matrix} \right] \left\{ \begin{matrix} \epsilon_{xx} \\ \epsilon_{yy} \\ \gamma_{xy} \\ \gamma_{yz} \\ \gamma_{zx} \end{matrix} \right\} \tag{7}$$

Where,

$$\bar{Q}_{11} = \bar{Q}_{22} = \frac{E}{(1-\nu^2)}, \quad \bar{Q}_{12} = \frac{\nu E}{(1-\nu^2)}, \quad \bar{Q}_{44} = \bar{Q}_{55} = \bar{Q}_{66} = G = \frac{E}{2(1+\nu)}$$

The GDEs of the plate are obtained using energy principle and expressed as:

$$\delta u_0 : \frac{\partial N_{xx}}{\partial x} + \frac{\partial N_{xy}}{\partial y} = 0 \tag{8}$$

$$\delta v_0 : \frac{\partial N_{xy}}{\partial x} + \frac{\partial N_{yy}}{\partial y} = 0 \tag{9}$$

$$\delta w_0: \frac{\partial^2 M_{xx}}{\partial x^2} + \frac{\partial^2 M_{yy}}{\partial y^2} + 2 \frac{\partial^2 M_{xy}}{\partial x \partial y} = N_{xx}^b \frac{\partial^2 w}{\partial x^2} + N_{yy}^b \frac{\partial^2 w}{\partial y^2} + 2 N_{xy}^b \frac{\partial^2 w}{\partial x \partial y} \tag{10}$$

$$\delta \phi_x: \frac{\partial M_{xx}^f}{\partial x} + \frac{\partial M_{xy}^f}{\partial y} - Q_x^f = 0 \tag{11}$$

$$\delta \phi_y: \frac{\partial M_{xy}^f}{\partial x} + \frac{\partial M_{yy}^f}{\partial y} - Q_y^f = 0 \tag{12}$$

Where,  $N_{xx}^b, N_{yy}^b$  are the in-plane forces and  $N_{xy}^b$  is the in-plane shear force. The force and moment resultants in the plate are expressed as:

$$N_{ij}, M_{ij}, M_{ij}^f = \int_{-h/2}^{+h/2} (\sigma_{ij}, z\sigma_{ij}, f(z)\sigma_{ij}) dz \tag{13}$$

$$Q_x^f, Q_y^f = \int_{-h/2}^{+h/2} (\sigma_{xz}, \sigma_{yz}) \left( \frac{\partial f(z)}{\partial z} \right) dz \tag{14}$$

Boundary condition for simply supported plate is expressed as

$$\begin{aligned} x = 0, a: N_{xx} = 0, v_0 = 0, w_0 = 0, M_{xx} = 0, \phi_y = 0 \\ y = 0, b: u_0 = 0, N_{yy} = 0, w_0 = 0, \phi_x = 0, M_{yy} = 0 \end{aligned} \tag{15}$$

### 3 SOLUTION METHODOLOGY

RBF-based meshfree method is one of the best and most powerful approaches to solve the system of PDEs with higher accuracy. The significant feature of the RBF-based meshfree method is that it does not require meshes. However, the method accuracy and stability are extremely dependent on an appropriate choice of a shape parameter ‘k.’ The modification of radial distance between the nodes for rectangular coordinates is done in such a way that the aspect ratio starts changing without changing the shape parameters. The expression used for square plate

$$r = \|X - X_j\| = \sqrt{(x - x_j)^2 + (y - y_j)^2} \text{ has been modified as } r = \|X - X_j\| = \sqrt{\left(\frac{x - x_j}{a}\right)^2 + \left(\frac{y - y_j}{b}\right)^2} \text{ for rectangular plate}$$

where a and b are the length and breadth of a rectangular plate. And various types of RBFs used in computational applications are listed in Table 1. The considered GDEs with five unknown variables  $u_0, v_0, w_0, \phi_x$  and  $\phi_y$  can be interpolated in the form of the modified radial distance between nodes. To eliminate the singularity, an infinitesimally small value is added for zero radial distance. All computational calculations are carried out in MATLAB with a 2.7 GHz Corei7 processor.

**Table 1: Various types of RBFs used in computation applications.**

S. No	RBFs
1	Polynomial, $g1 = r^k$
2	Gaussian quadratic, $g2 = e^{(-k^2 r^2)}$
3	Thin Plate Spline, $g3 = \log(r) r^{2k}$
4	Wendland’s C2, $g4 = (1 - kr)^4 (4kr + 1)$
5	Wendland’s C4, $g5 = (1 - kr)^6 \left( (35(kr)^2) + (18kr) + 3 \right)$
6	Wendland’s C6, $g6 = (1 - kr)^8 \left( (32(kr)^3) + (25(kr)^2) + (8kr) + 1 \right)$
7	Hyperbolic secant, $g7 = \text{sech}(k\sqrt{r})$
8	Wu-C2, $g8 = (1 - kr)^5 \left( 8 + 40kr + 48(kr)^2 + 25(kr)^3 + 5(kr)^4 \right)$

9	$Wu-C4, g9 = (1 - kr)^6 (6 + 36kr + 82(kr)^2 + 72(kr)^3 + 30(kr)^4 + 5(kr)^5)$
10	Hardy's Multiquadric, $g10 = \sqrt{(k^2 + r^2)}$
11	Hardy's Inverse Quadric $g11 = (k^2 + r^2)^{-1}$
12	Inverse Multi-quadric, $g12 = (\sqrt{1 + (kr)^2})^{-1}$
13	Generalized Inverse Multi-quadric, $g13 = (1 + (kr)^2)^{-2}$

The convergence of results was checked by shifting the shape parameter. When convergence is confirmed and stable, the accuracy is likewise checked. Also, in view of stability and accuracy, the authors calculate the shape parameter. The discretization of GDEs for five unknown variables is considered by. The value of 'p' is also optimized for accuracy, and it is found that 'p=0.9' is a better choice.

### 4 RESULTS AND DISCUSSION

In this section, various numerical examples are presented and discussed to verify the convergence and accuracy of the present theory and RBFs for predicting the buckling analysis of simply supported FGM plates. The material properties of FGM used in computing results are  $E_c=360$  GPa,  $E_m=70$  GPa,  $\nu=0.3$ .

#### 4.1 Convergence study

The first example is performed for the convergence study of the rectangular FGM plate. The obtained results by thirteen RBFs are compared with 2-D HSDT via Navier-type analytical solutions [112] and quasi-3D via Navier solution.[113] The aspect ratio is taken as 0.5 with grading index=2. From Table 2, it is observed that all the results obtained by modifying RBFs are in good agreement with the 2-D HSDT and 3-D HSDT result of rectangular FGM plate under uniaxial load. In 15x15 nodes, the convergence rate % is less than 1% for all the RBFs. So, 15x15 nodes are considered throughout the study.

#### 4.2 Comparison study

To check the accuracy and effectiveness of the present methodology, various comparison study has been done for the buckling analysis of the FGM plate. Table 3 shows the comparison study of an isotropic rectangular plate with the 3D result via differential quadrature [114] under biaxial load. The span to thickness ratio is 10. When the thirteen RBFs are compared to 3D results via differential quadrature [114], it can be observed that as the aspect ratio increase from 1 to 2, the diff % decreases for all the RBFs. All the RBFs are in good agreement with the 3D result via differential quadrature result in the literature.

**Table 1: Convergence and validation study of normalized buckling  $\bar{N}_{cr} = N_{cr} a^2 / E_m h^3$  of rectangular FGM plate under uniaxial load ( $a/b=0.5, n=2, a/h=20$ )**

Where Avg. Diff %= Abs ((Ref. results -Present result-)/ Ref. result) x100

Table 4 shows the effect of grading index and RBFs on normalized buckling of FGM plate under uniaxial load. Aspect ratio is taken as 0.5 with a span to thickness ratio is 10. The RBFs results are compared with the 2-D HSDT [112], and 3-D HSDT [113] result in the literature. It can be observed that RBFs g1, g4, g5, g11, g12 and g13 predict a good result as compared to 2-D HSDT [112]. g1 and g10 predict higher average diff %. It can also be seen that normalized buckling decrease by increasing the value of the grading index.

It can also be seen that normalized buckling decrease by increasing the value of the grading index.

**Fig 1: Comparison study for RBFs with span to thickness ratio on normalized buckling  $\bar{N}_{cr} = N_{cr} a^2 / E_m h^3$  of FGM plate under biaxial load.**

Figure 1 presents the variation of normalized buckling in terms of RBFs and span to thickness ratio. Aspect ratio is taken as 0.5 and grading index is 0.5. It can be noticed that g2 and g10 under predict with 2-D HSDT via Navier-type analytical solutions and quasi-3D via Navier solution for all span to thickness ratio. g11, g12 and g13, over predicts the HSDT and under predict with the quasi-3D z results. Overall, the present methodology is good for analysing the rectangular plate. It can also be observed that by increasing the span to thickness ratio, normalized buckling also increased.

**Fig 2: Comparison study of RBFs with computational speed**

Now the comparison study of all RBFs with the time taken to compute the buckling results. From Figure 2, it can

be observed that g2, g10, g11, g12, and g13 take less computational time as compared to other RBFs and g9 takes maximum time.

### 4.3 Parametric study

#### 4.3.1 Effect of grading index with an aspect ratio

In this section, the effect of aspect ratio on normalized buckling of FGM plate ( $a/h=10$ , g11) under biaxial loading is investigated and presented in Table 5. It is observed that by increasing the grading index for all aspect ratio and modes, normalized buckling decreases. It is also noticed that normalized buckling also increases by increasing the aspect ratio. Figure 3 represents the effect of grading index on normalized buckling of FGM plate under uniaxial loading ( $a/b=0.5,1$ ). It is noticed that by increasing the grading index for  $a/b=0.5$  and  $a/b=1$ , the normalized buckling decreases, and after  $n=5$ , the effect of the grading index is constant.

**Table 5: Effect of aspect ratio on normalized buckling  $\bar{N}_{cr} = N_{cr} a^2 / E_m h^3$  of FGM plate under biaxial loading.**

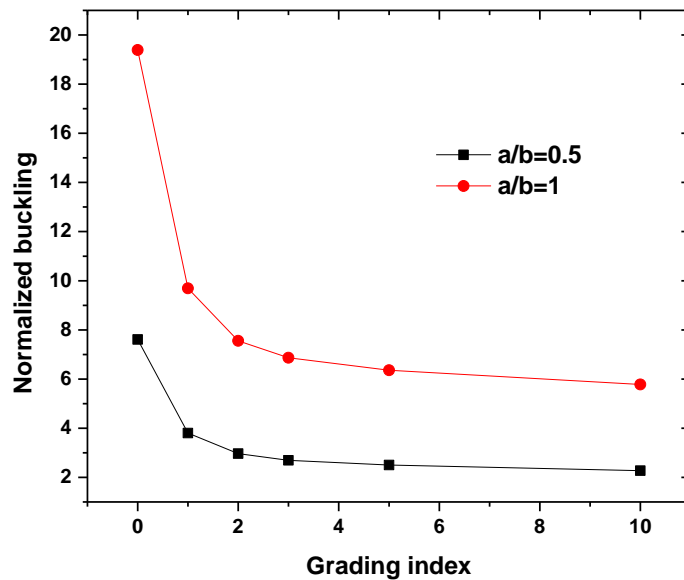

Fig 3: The effect of grading index on normalized buckling  $\bar{N}_{cr} = N_{cr} a^2 / E_m h^3$  of FGM plate under uniaxial loading.

4.3.2 Effect of span to thickness ratio with an aspect ratio

Now, the effect of span to thickness ratio with different aspect ratios for normalized buckling of FGM plate (n=2, g 12) under biaxial loading is investigated and shown in Figure 4. It is observed that all the aspect ratio shows the same nature, and by increasing the span to thickness ratio, normalized buckling also increases, and after a/h=50, the influences of a/h is constant. It is also noted that normalized buckling increases by increasing the aspect ratio.

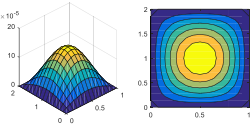

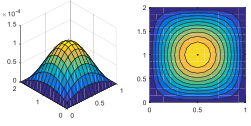

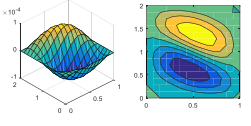

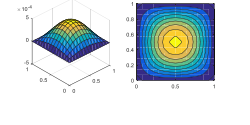

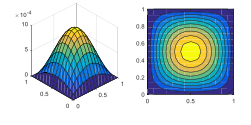

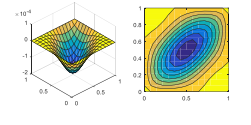

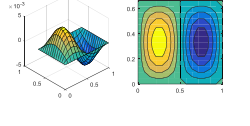

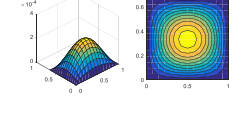

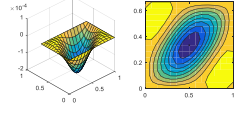

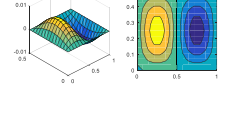

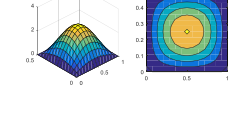

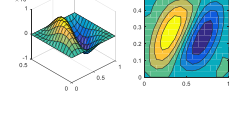

Fig 4: The effect of span to thickness ratio with aspect ratio on normalized buckling  $\bar{N}_{cr} = N_{cr} a^2 / E_m h^3$  of FGM plate under biaxial loading.

4.3.2 Effect of in-plane loading with aspect ratio.

Table 6 represents the effect of aspect ratio on normalized buckling  $\bar{N}_{cr} = N_{cr} / E_m h^3$  of FGM plate (a/h=10,

$n=1, g=11$ ) under uniaxial, biaxial and pure shear loading. It is observed that by increasing the aspect ratio, normalized buckling increases for all the loading. Pure shear loading predicts maximum normalized buckling as compared to another loading.

**Table 6 Normalized buckling and counters shape of FGM plate under various types of loading**

a/b	Uniaxial loading	Biaxial loading	Pure shear loading
0.5	 <p>3.719</p>	 <p>2.97</p>	 <p>14.44</p>
1	 <p>9.36</p>	 <p>4.68</p>	 <p>19.6584</p>
1.5	 <p>20.876</p>	 <p>7.39</p>	 <p>30.882</p>
2	 <p>33.03</p>	 <p>10.96</p>	 <p>44.48</p>

### 5 CONCLUSIONS

Thirteen RBFs have been compared for buckling behaviour of rectangular FGM plate obtained from five variables higher-order shear deformation theory. The benchmark results from the literature verify the effectiveness of the modified RBFs. The computational speed of RBFs  $g_2, g_{10}, g_{11}, g_{12}$ , and  $g_{13}$  is reasonable as compared to other RBFs taken here. It also concluded that modified radial distances in RBFs are helpful in predicting the buckling response of rectangular plates with different aspect ratios, which was not obtained without changing the radial distance of RBFs. It is observed that normalized buckling load decreases with an increase in  $a/b$  and grading index; however, it increases as the span to thickness ratio increases.
